## Mapping

No viewpoint

## Documentation

This view describes how based upon events, a User journey map can be constructed to be interpreted by a User journey manager.

Our story starts with the eventlog. How this log came to be is not the concern of this architecture. The log contains different events and is possibly enhanced to represent STEM aspects.

S: Sentiment

T: Topic

E: Emotion

M: Motivation

On top of that extra events can be deduced from text.

The STEM enhanced eventlog in turn is used to build a model that can be viewed.

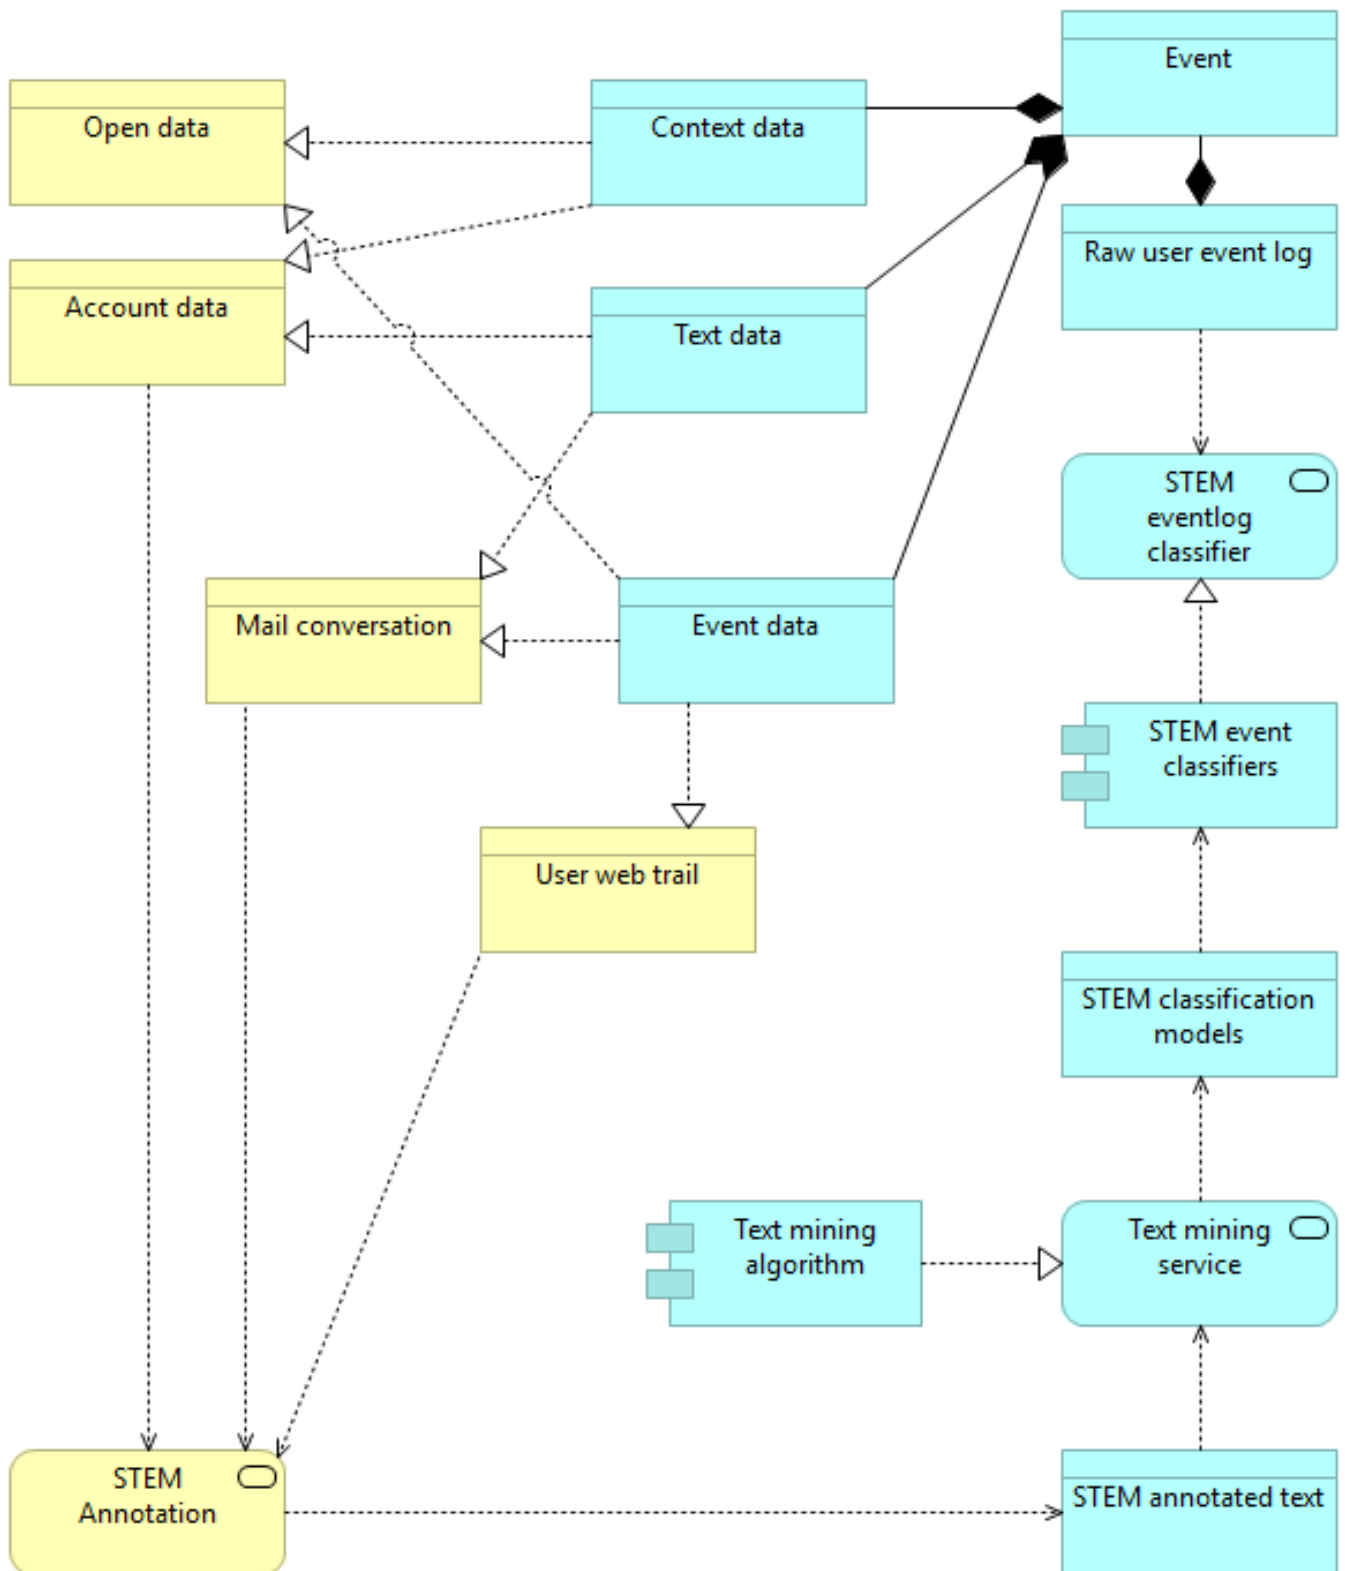

## Elements

Element	Type
Context data	Data Object
Event	Data Object
Event data	Data Object
Process miner	Application Component
Raw user event log	Data Object
STEM enhanced user eventlog	Data Object
STEM eventlog classifier	Application Service
Text data	Data Object
User journey manager	Business Actor
User journey map	Business Object
User story miner	Application Service
User story model	Data Object

# Parameterization

No viewpoint

## Documentation

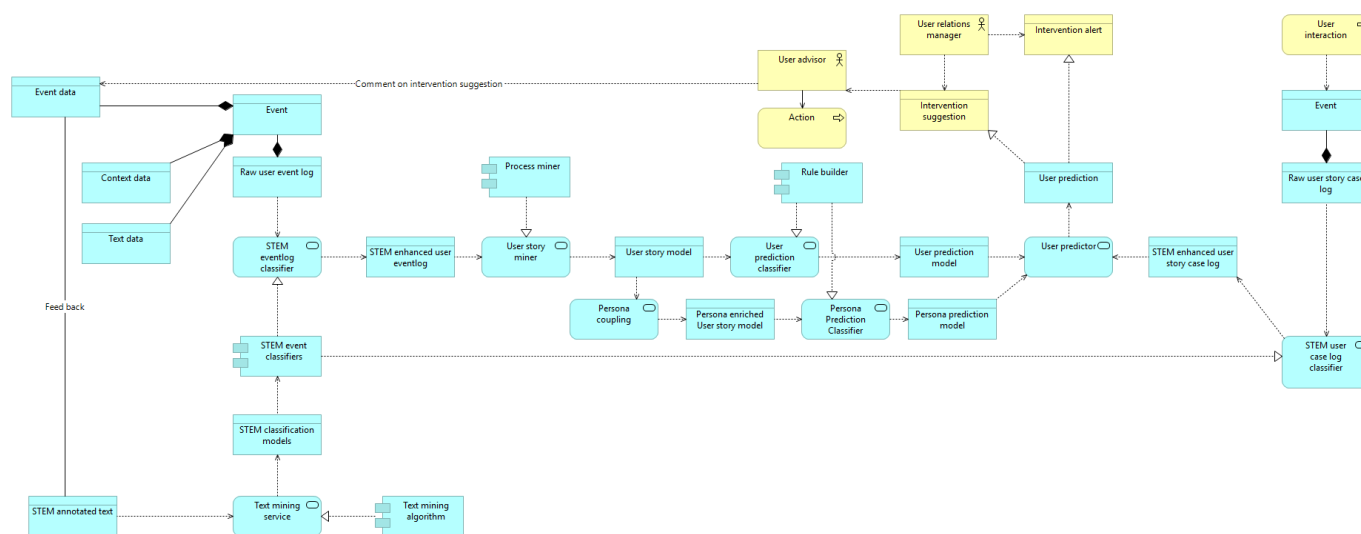

To enable Mapping and Prediction the STEM eventlog classifier needs classification models. These models describe how to classify a text for one of the aspects.

The models are built by using text mining. For this to succeed, annotated text is needed. This can be created manually by adding annotations to domain relevant text quotations.

## Elements

Element	Type
Account data	Business Object
Context data	Data Object
Event	Data Object
Event data	Data Object
Mail conversation	Business Object
Open data	Business Object
Raw user event log	Data Object
STEM annotated text	Data Object
STEM Annotation	Business Service
STEM classification models	Data Object
STEM event classifiers	Application Component
STEM eventlog classifier	Application Service
Text data	Data Object
Text mining algorithm	Application Component
Text mining service	Application Service
User web trail	Business Object

## Prediction No viewpoint

## Documentation

Prediction is used to inform agents in the organization real time about specific user story cases that are not going as intended or to even suggest ways to improve the remainder of the case.

For a large part prediction builds on functionality also used for Mapping the user journey. You can see this on the left. The same User story model is created but from there something else follows.

The User story model itself is used to build rules that enable to predict user behavior based on past behavior. This can be done directly based on the User story model which results in a User prediction model. It is also possible to enhance the User story model manually so that a distinction between different persona is made. This results in a Persona prediction model.

Both models can be used to predict user behavior based on already recorded behavior in the form of a user story case log. Based on these predictions intervention alerts and intervention suggestions can be created.

## Elements

Element	Type
Action	Business Process
Context data	Data Object
Event	Data Object
Event data	Data Object
Intervention alert	Business Object
Intervention suggestion	Business Object
Persona coupling	Application Service
Persona enriched User story model	Data Object
Persona Prediction Classifier	Application Service
Persona prediction model	Data Object

<b>Element</b>	<b>Type</b>
Process miner	Application Component
Raw user event log	Data Object
Raw user story case log	Data Object
Rule builder	Application Component
STEM annotated text	Data Object
STEM classification models	Data Object
STEM enhanced user eventlog	Data Object
STEM enhanced user story case log	Data Object
STEM event classifiers	Application Component
STEM eventlog classifier	Application Service
STEM user case log classifier	Application Service
Text data	Data Object
Text mining algorithm	Application Component
Text mining service	Application Service
User advisor	Business Actor
User interaction	Business Process
User prediction	Data Object
User prediction classifier	Application Service
User prediction model	Data Object
User predictor	Application Service
User relations manager	Business Actor
User story miner	Application Service
User story model	Data Object

# Business Layer

## Account data

<b>Type</b>	Business Object
-------------	-----------------

Information about a specific user or account that can be useful to interpret actions of the user or agents of the organization.

## Action

<b>Type</b>	Business Process
-------------	------------------

Actions taken by the User advisor.

## Intervention alert

<b>Type</b>	Business Object
-------------	-----------------

An intervention alert, alerts a User relations manager so that he can intervene.

## Intervention suggestion

<b>Type</b>	Business Object
-------------	-----------------

Suggestion to the User advisor on how to act towards the user.

## Mail conversation

<b>Type</b>	Business Object
-------------	-----------------

Event log where successive mails are events.

## Open data

<b>Type</b>	Business Object
-------------	-----------------

Event data like tweets on twitter or other information that might explain behavior of users like the weather on a specific day and location.

## STEM Annotation

<b>Type</b>	Business Service
-------------	------------------

Annotating text with STEM specific annotations.

S: Sentiment

T: Topic

E: Emotion

M: Motivation

## User advisor

<b>Type</b>	Business Actor
-------------	----------------

## User interaction

<b>Type</b>	Business Process
-------------	------------------

Users interacting through touch points creates events.

## User journey manager

<b>Type</b>	Business Actor
-------------	----------------

Manages the user journey for the users

## User journey map

<b>Type</b>	Business Object
-------------	-----------------

Visualization of the User story model. Of course multiple visualizations of the same model are possible because of the multi dimensionality of the User story model.

## User relations manager

<b>Type</b>	Business Actor
-------------	----------------

## User web trail

<b>Type</b>	Business Object
-------------	-----------------

Event log that shows relevant click events from the user.

# Application Layer

## Context data

<b>Type</b>	Data Object
-------------	-------------

Attributes data that is relevant to the event or to a whole case but is not directly related to the event itself.

## Event

<b>Type</b>	Data Object
-------------	-------------

Refers to one activity instance related to one process instance (case) and one timestamp; event refers to a case, an activity instance, and a point in time; events have attributes; events have a name (the classifier of the event), which default is the activity it refers to, but that is not mandatory;

## Event data

<b>Type</b>	Data Object
-------------	-------------

Attributes structured data directly related to the event

## Persona coupling

<b>Type</b>	Application Service
-------------	---------------------

Using the user story model, specific paths are associated with specific persona.

## Persona enriched User story model

<b>Type</b>	Data Object
-------------	-------------

A User Story Model where certain paths are annotated with persona information.

## Persona Prediction Classifier

<b>Type</b>	Application Service
-------------	---------------------

A classifier that builds rules that enable to detect what kind of persona is involved in a specific user story.

## Persona prediction model

<b>Type</b>	Data Object
-------------	-------------

A set of rules that enable automatic prediction of the persona involved in a specific user story.

## Process miner

<b>Type</b>	Application Component
-------------	-----------------------

Process mining solutions like ProM or BupaR or their commercial counterparts.

## Raw user event log

<b>Type</b>	Data Object
-------------	-------------

The raw user event log contains all data relating to events in the user stories that was obtained from various sources. Creating the event log is not part of this architecture because this is specific to the organizations providing the log.

## Raw user story case log

<b>Type</b>	Data Object
-------------	-------------

The Raw user story case log contains all data relating to events in a specific user story that was obtained from various sources. Creating the Raw user story case log is not part of this architecture because this is specific to the organizations providing the log.

## Rule builder

<b>Type</b>	Application Component
-------------	-----------------------

## STEM annotated text

<b>Type</b>	Data Object
-------------	-------------

To create text classification models annotated text is used.

## STEM classification models

<b>Type</b>	Data Object
-------------	-------------

There are different types of classification that are used to enhance the eventlog with additional knowledge that can be mined from text:

S: Sentiment

T: Topic

E: Emotion

M: Motivation

On top of that extra events can be deduced from text.

The STEM event classification models each support specific classifications. For readability of the model these are modeled as one.

## STEM enhanced user eventlog

<b>Type</b>	Data Object
-------------	-------------

This eventlog contains the structured information from the Raw user event log and in addition the now structured data obtained from Text data through the use of the STEM eventlog classifier.

## STEM enhanced user story case log

<b>Type</b>	Data Object
-------------	-------------

This case log contains the structured information from the Raw user story case log and in addition the now structured data obtained from Text data through the use of the STEM eventlog classifier.

## STEM event classifiers

<b>Type</b>	Application Component
-------------	-----------------------

There are different types of classification that are used to enhance the eventlog with additional knowledge that can be mined from text:

S: Sentiment

T: Topic

E: Emotion

M: Motivation

On top of that extra events can be deduced from text.

The STEM event classifiers each perform specific classifications. For readability of the model these different classifiers are modeled as one.

## STEM eventlog classifier

<b>Type</b>	Application Service
-------------	---------------------

There are different types of classification that are used to enhance the eventlog with additional knowledge that can be mined from text:

S: Sentiment

T: Topic

E: Emotion

M: Motivation

On top of that extra events can be deduced from text.

The STEM eventlog classifier bundles the functionality of the different underlying classifiers.

## STEM user case log classifier

<b>Type</b>	Application Service
-------------	---------------------

There are different types of classification that are used to enhance the eventlog with additional knowledge that can be mined from text:

S: Sentiment

T: Topic

E: Emotion

M: Motivation

On top of that extra events can be deduced from text.

The STEM user case log classifier bundles the functionality of the different underlying classifiers.

## Text data

<b>Type</b>	Data Object
-------------	-------------

Text data usually relates directly to a single event and in that way it can be viewed upon as unstructured event data. It can however relate to multiple events and even to events that are not in the raw user eventlog.

## Text mining algorithm

<b>Type</b>	Application Component
-------------	-----------------------

Text mining as a broad concept is used for different aspects of STEM classification. Different algorithms will be used but are modeled as one to maintain readability of the model. Usually supported learning algorithms are used.

## Text mining service

<b>Type</b>	Application Service
-------------	---------------------

Text mining as a broad concept is used for different aspects of STEM classification. Different services will be used but are modeled as one to maintain readability of the model.

## User prediction

<b>Type</b>	Data Object
-------------	-------------

Prediction of the most likely next steps. Based on this an advice or an intervention alert can be given.

## User prediction classifier

<b>Type</b>	Application Service
-------------	---------------------

A classifier that builds rules to classify the expected next step from the user.

## User prediction model

<b>Type</b>	Data Object
-------------	-------------

A set of rules that enable automatic prediction of the next step in a specific customer story.

## User predictor

<b>Type</b>	Application Service
-------------	---------------------

A prediction algorithm that uses the User prediction model and / or the Persona prediction model to predict the most likely next steps. Based on this an advice or an intervention alert can be given.

## User story miner

<b>Type</b>	Application Service
-------------	---------------------

Mines eventlogs and creates models / a model that represent the historic user stories.

## User story model

<b>Type</b>	Data Object
-------------	-------------

The user story model is a model that "shows" the different user stories as a process.

# Relations
